Appendix B

Data Definitions and Sources for Elections and Election Monitors

All election data were compiled from two existing datasets on election events between 1990 and 2004. Because the election event data are not annual, they were converted to annual observations if any election in a given country-year met the criteria described below.

Election

The *Election* variable represents a dichotomous indication of whether or not an election for national level office took place, and in which multiparty competition was technically possible. It was coded from three questions from the ___ data that serve as a competitive election screen. Elections with no opposition political parties allowed or competing, or with no choice of candidates on the ballot are not considered competitive elections. This competitive elections screen is intentionally not based on evaluations of the relative “closeness” of the vote share or aggregate democracy scores such as Polity or Freedom House, and allows for the possibility of elections with very popular incumbent parties as well as competitive elections in regimes with low levels of democracy or restricted political and civil rights.

Inter-coder reliability. The election data were coded by a team of undergraduate RAs. Approximately 16% percent of the election events were coded twice by different RAs to assess the rate of inter-coder reliability. For the three questions used in this paper, rates of inter-coder agreement were consistently high.

Q3. Was opposition allowed? For yes/no coding, 94% agreement between coders. For yes/no/unknown/unclear coding, 91% agreement.

Q4. Was more than one party legal? For yes/no coding, 97% agreement between coders. For yes/no/unknown/unclear coding, 96% agreement.

Q5. Was there a choice of candidates on the ballot? For yes/no coding, 98% agreement between coders. For yes/no/unknown/unclear coding, 97% agreement.

Monitored Election

Data on monitored elections were coded by the author, as presented in _____. For all elections, *Monitored Election* is coded as one if an official delegation of foreign observers was present to observe and report on the electoral process. In this paper, “friendly” international observers who are extremely unlikely to criticize any election fraud or manipulation are excluded, as these rubber stamp delegations are unlikely to constrain the ability of governments to manipulate elections (as our theory requires). Therefore, for an election to count as internationally monitored in these data, the organization must have previously observed and criticized an election. Once an international observer organization has condemned a fraudulent election, this coding assumes that from that point forward, their reputation should be known to other leaders who invite them.

Discussion of IMF Selection Model

The selection model for *IMF Hazard Rate* builds upon Nooruddin and Simmons' (2006) model of IMF program participation. The dependent variable is *Under IMF Agreement*. The independent variables are one period lags of *Under IMF Agreement*, *GDP per capita*, *GDP Growth*, *Current Account Balance*, *Government Balance*, and *POLITY*. Current Account Balance is from World Bank (2007). Regime type data are from the POLITY IV dataset (Marshall and Jaggers 2002). Following common practice, the analysis uses the 21 point scale ranging from -10 (strongly autocratic) to 10 (strongly democratic), with higher scores indicating more democratic political institutions.

Nooruddin and Simmons include a lag of IMF program participation in their model to account for IMF program recidivism. IMF recidivism is a key theoretic argument for increased future IMF program participation, and one of the strongest empirical findings in the IMF literature (Conway 2007). For substantive reasons (rather than to control for temporal dependence), including a variable for past IMF participation is the preferred modeling strategy in the field (see, for example, IMF 2003, Nooruddin and Simmons 2006, Pop-Eleches 2008, Przeworski and Vreeland 2000, Stone 2008, and Vreeland 2002). Based on recent literature, failing to account for past IMF program participation would result in a model that is not reflective of the field's understanding of the causes of IMF program participation. We present three different versions of this model to account for the potential problem of temporal dependence found in time-series data with a binary dependent variable. In model 1, we follow Nooruddin and Simmon's specification and do not explicitly model temporal dependence. In

model 2, we adopt Beck, Katz and Tucker's (1998) recommendation to take time seriously by including a three cubic splines in our analysis. In model 3, we include *Count*—which is an annual count variable coded 1 in 1990, 2 in 1991, etc., $Count^2$, and $Count^3$, which captures Carter and Signorino's (2007) recommendation that models with temporal dependence and binary dependent variables include variables that capture time, time squared, and time cubed, which they argue represent a flexible and transparent method for dealing with temporal dependence and binary data.

A probit estimator is used to estimate the hazard rate instead of the linear probability model used by Nooruddin and Simmons. Nooruddin and Simmons (2006) adopt a linear probability estimator to replicate the results presented in IMF (2003). Their results hold when estimated with dynamic probit and dynamic bivariate probit with partial observability models (Nooruddin and Simmons 2006, 1017 fn57).

Table D1: IMF Selection Models

	Model 1	Model 2	Model 3 (Used in Paper)
Resulting IMF Hazard Rate:	1	2	3
Temporal dependence correction:		Cubic Splines	Year, Year ² , Year ³
Under IMF Agreement, lagged	2.10 ** (0.10)	1.82 ** (0.13)	2.11 ** (0.10)
GDP per capita, lagged	-0.14 * (0.05)	-0.10 ^ (0.06)	-0.13 * (0.06)
GDP Growth, lagged	-0.02 ^ (0.01)	-0.02 ^ (0.01)	-0.02 ^ (0.01)
Current Account, lagged	-0.02 * (0.01)	-0.02 * (0.01)	-0.02 ** (0.01)
Government Balance, lagged	0.00 (0.01)	-0.01 (0.01)	0.00 (0.01)
POLITY, lagged	0.01 (0.01)	0.01 (0.01)	0.02 ^ (0.01)
Spline 1		0.12 * (0.06)	
Spline 2		0.03 ** (0.01)	
Spline 3		-0.27 * (0.13)	
Year			-0.13 (0.14)
Year ²			0.01 (0.02)
Year ³			0.00 (0.00)
Constant	-0.13 (0.40)	-0.09 (0.40)	0.19 (0.47)
Pseudo R2	0.44	0.46	0.45
